

Direct circulation rotary drilling rigs

How does direct circulation drilling work?

For direct circulation drilling, the drilling fluid is circulated from the drill stem and then flows up the annulus between the outside of the drill stem and borehole wall. The drilling fluid that carries the drill cuttings flows to the surface and the subsequent settlement pits.

What is the difference between direct circulation drilling and reverse circulation drilling?

For direct circulation drilling and reverse circulation drilling, the major difference in drilling method is related to the direction of movement of drilling fluid. For direct circulation drilling, the drilling fluid is circulated from the drill stem and then flows up the annulus between the outside of the drill stem and borehole wall.

How does a reverse circulation drill work?

Pumps are employed to lift the cuttings free fluid back to the drill stem. For reverse circulation drilling, the direction of flow of drilling fluid is opposite to that of direct circulation drilling. Drilling fluid flows from the annulus between the drill stem and hole wall to the drill stem.

How deep can a rotary rig Drill?

Reverse Circulation Mud Rotary Rig is powered by single/double engine and rated to drill 18" to 60" Dia. hole 400 feet to 600 feet deep using the centrifugal pump. Deeper holes are possible with Air injection equipment. Our Rigs are ideal for DTH Drilling, Air Rotary Drilling, and Mud Rotary Drilling etc.

What are rotary drilling rigs?

Rotary drilling machines are state-of-the-art drilling tools with complex machinery and design. For the sake of ease, we are going to briefly discuss the seven major components of conventional rotary drilling rigs. 1. Drill String

What is air rotary drilling?

Air rotary drilling is a method used to drill deep boreholes in rock formations. Borehole advancement is achieved by the rapid rotation of a drill bit which is mounted at the end of the drill pipe. The drill bit "cuts" the formation into small pieces, called cuttings.
