It goes without saying that well control is essential. When drilling, there are many indicators that can be used to determine if the well may kick.

These warning signs (secondary indicators) include abrupt increase in the rate of penetration while drilling called a drilling break, increase in torque and drag, changes in mud properties, ...

Kick Detection trains the student to detect drilling kicks as early as possible. This course illustrates the significance of formation porosity and permeability in the development of a drilling kick. It ...

The purpose of these BOP & Well Control drills procedures or exercises is to familiarize rig personnel with the various equipment and with ...

A "positive" drilling break (or increase in ROP) is usually a warning sign that requires a flow check, as the new formation may be more porous than previous formations, meaning that the ...

Positive kick (wellbore influx) indications mean signs showing almost 100% kick (wellbore influx) into wellbore. Positive Kick Indicators While ...

Early kick detection is of great concern while drilling wells. The late kick detection can lead to uncontrolled blowout which increases the possibility ...

When drilling deep horizontals, most conventional kick warning signs no longer apply. In fact, pit volume gains often are the only sign the well is kicking, and ...

MPD used some specialized tools and techniques to enhance traditional kick detection capabilities and circulate formation influx while keeping NPT at the minimum level. ...

The only way to positively identify a kick is to turn off the pump, wait for the well to stabilize, and then observe the annulus for flow. Positive flow indicates that formation fluids are likely ...
