How does a screw compressor work?

A screw compressor can run loaded ('pumping air') or unloaded ('idle'). The inlet/loading valve opens and closes according to air demand. The inlet valve is controlled by a solenoid valve that supplies control air to the inlet/loading valve. Check solenoid valve coil and solenoid valve operation.

How does a pressure relief valve work?

Pressure relief valves control and limit the pressure build-up in an air compressor system. If pressure exceeds what the pressure relief valve allows, the valve will automatically open and release air until the pressure reduces. Uncontrolled pressure from an air tank or compressor can damage downstream components if the pressure gets too high.

How does a compressor unloader valve work?

The unloader valve responds to the pressure changes inside the compressor's storage tank. When the tank pressure reaches the maximum preset pressure, the pressure switch flips a small lever on the switch, which triggers the unloader valve to open and vent the pressurized air.

What is a minimum pressure valve?

The minimum pressure valve is a check valve that ensures minimum pressure in the internal system of the air compressor. It is one of the most important air compressor valve types. Primarily, it ensures the system maintains a minimum operating pressure to lubricate the air compressor and stabilize the compressor output.

What happens if a compressor is not generating minimum pressure?

When the system is not generating minimum pressure, the minimum pressure valve stays closed, effectively becoming a barrier between the oil circulation system and the compressed air reservoir. When the compressor reaches the necessary pressure, the minimum pressure valve opens, allowing the mixed air and oil to enter the separator.

How do air compressor pressure relief valves work?

The air compressor pressure relief valve is set above the high-pressure switch and generally set at or below the vessel's maximum operating pressure. Pressure relief valves open proportionally to the pressure increase above the setpoint, and close gradually. Safety valves open and blow off immediately upon the system pressure reaching the setpoint.
